# COMP 2012 Midterm Exam - Spring 2016 - HKUST

Date: April 2, 2016 (Saturday)

Time Allowed: 2 hours, 2-4pm

Instructions: 1. This is a closed-book, closed-notes examination.

- 2. There are  $\underline{9}$  questions on  $\underline{24}$  pages (including this cover page).
- 3. Write your answers in the space provided in black/blue ink. *NO pencil please, otherwise you are not allowed to appeal for any grading disagreements.*
- 4. All programming codes in your answers must be written in the ANSI C++ version as taught in the class.
- 5. For programming questions, you are <u>NOT</u> allowed to define additional helper functions or structures, nor global variables unless otherwise stated. You also <u>cannot</u> use any library functions not mentioned in the questions.

#### Problem 1 [10 points] True or false

Indicate whether the following statements are true or false by <u>circling</u> **T** or **F**. You get 1.0 point for each correct answer, -0.5 for each wrong answer, and 0.0 if you do not answer.

- T F (a) Both class member functions and global functions can be inline functions.
- **T F** (b) Both class member functions and global functions can be const functions.
- **T F** (c) Slicing works for public, protected and private inheritance. That is, you may always assign a derived class object to a base class object regardless of whether the derived class is derived from the base class using public, protected and private inheritance.
- **T F** (d) The prototype of the copy constructor for a class X generally is

```
X::X(const X& obj_to_copy);
```

Actually the following form is also fine:

```
X::X(X obj_to_copy);
```

- **T F** (e) A class with virtual destructor is intended to be used as a base class.
- **T F** (f) In the following class, author will be constructed before title:

```
#include "Title.h"
#include "Author.h"
class Book
{
   public:
      Book(): author("J.K.Rowling"), title("Harry Potter") { }
   private:
      Title title;
      Author author;
};
```

**T F** (g) There is no dynamic binding for virtual functions in constructors or destructors.

**T F** (h) Passing a data member as a parameter in the member initialization list is dangerous because the data member will not have been properly initialized. For instance, the constructor War\_Game in the following is potentially error-prone:

```
#include "Game.h"
#include "Player.h"
class War_Game : public Game
{
   public:
      War_Game() : Game(player) {}
   protected:
      Player player;
};
```

**T F** (i) A global function that takes an object of type A can be called on an object of type B as long as A has a conversion constructor that can convert a B object to an A object. One example is shown below and it is expected to run with no error.

```
/* Assume class B has been defined here */
class A
{
   public:
    A() {}
    A(const B& b) {}
};

void do_something(A a) {}

int main()
{
   B b;
   do_something(b);
   return 0;
}
```

**T F** (j) Since one cannot create objects out of an abstract base class, it cannot have constructor(s) and destructor.

#### Problem 2 [8 points] Constness

In the following program, for the 16 statements ending with the following comment:

```
/* Error: Yes / No / Don't know */
```

decide whether the statement is syntactically INCORRECT — that is, it will produce compilation error(s). <u>Circle</u> "Yes" if it will give compilation error and "No" otherwise.

You get 0.5 point for each correct answer, -0.25 for each wrong answer, and 0.0 if you do not answer by circling "Don't know".

```
#include <iostream>
using namespace std;
class Anything {
 public:
    void set(int k) { data = k; }
    int get( ) const { return data; }
 private:
    int data;
};
void print1(Anything& a) { cout \ll a.get() \ll endl; }
void print2(const Anything& a) { cout ≪ a.get() ≪ endl; }
int main( ) {
    Anything x;
    Anything *const cpx = &x;
                                               /* Error: Yes / No / Don't know */
    const Anything* pcx = &x;
                                               /* Error: Yes / No / Don't know */
    const Anything *const cpcx = &x;
                                               /* Error:
                                                           Yes
                                                                / No / Don't know */
                                                                           Don't know */
    cpx \rightarrow set(1);
                                                   Error:
                                                           Yes
                                                                / No /
    pcx \rightarrow set(2);
                                                   Error:
                                                           Yes / No / Don't know */
                                                           Yes
                                                                / No / Don't know */
    cpcx \rightarrow set(3);
                                                   Error:
                                                                / No / Don't know */
    print1(x);
                                                /* Error: Yes
    print2(x);
                                                /* Error: Yes / No / Don't know */
    const Anything y;
    Anything *const cpy = &y;
                                               /* Error: Yes / No / Don't know */
    const Anything* pcy = &y;
                                                           Yes
                                                                / No / Don't know */
                                               /* Error:
    const Anything *const cpcy = &y;
                                                           Yes
                                                               / No / Don't know */
    cpy \rightarrow set(1);
                                                   Error:
                                                          Yes
                                                                / No / Don't know */
                                                                / No / Don't know */
    pcy \rightarrow set(2);
                                                /* Error:
                                                           Yes
                                               /* Error: Yes / No / Don't know */
    cpcy \rightarrow set(3);
    print1(y);
                                                /* Error: Yes / No / Don't know */
    print2(y);
                                                /* Error: Yes / No / Don't know */
}
```

# Problem 3 [5 points] Member Initialization

The following classes miss constructors. Write <u>one</u> constructor (which might not be unique) for each class so that the classes can be compiled without errors.

```
(a) [3 points]
  class Base
{
    private:
        int b;
        int& ref;
    public:
        // Write your constructor in the space provided below
};
```

Answer:

Answer:

## Problem 4 [7 points] Order of Construction & Destruction

```
#include <iostream>
using namespace std;
class Wrapper
  private:
    int value;
  public:
    Wrapper(int \ v) : value(v) \{ cout \ll "Wrapper: " \ll value \ll endl; \}
    \simWrapper() { cout \ll "\simWrapper: "\ll value \ll endl; }
    int get() const { return value; }
};
class Info
  private:
    Wrapper data;
  public:
    Info(const\ Info\&\ x): data(x.data.get() + 10) \{ cout \ll "Info: Copy" \ll endl; \}
    \simInfo() { cout \ll "\simInfo" \ll endl; }
};
void tricky(Info oops)
{
    Info q = oops;
    \mathrm{cout} \ll \texttt{"After tricky"} \ll \mathrm{endl};
}
int main( )
{
    Info x(1);
    cout \ll "Call tricky" \ll endl;
    tricky(x);
    return 0;
}
```

## Problem 5 [9 points] Type and Order of Construction & Destruction

```
#include <iostream>
using namespace std;
class A
  private:
     int x;
  public:
     A(): x(0) \{ cout \ll "Default: " \ll x \ll endl; \}
     A(int n) : x(n) \{ cout \ll "Conversion: " \ll x \ll endl; \}
     A(\text{const } A\& \ a): x(a.x) \ \{ \ \text{cout} \ll "Copy: \ " \ll x \ll endl; \ \}
     \sim A() { cout \ll "\sim A: " \ll x \ll endl; }
};
A fun(A\& a)
{
     cout \ll "Fun!" \ll endl;
     {
          A obj;
     }
     return a;
}
int main( )
{
     A a(10);
     A b = a;
    A c[3];
    c[2] = \operatorname{fun}(c[1]);
    return 0;
}
```

# Problem 6 [8 points] Type of Inheritance

```
/* File: inheritance-type.cpp */
#include <iostream>
using namespace std;
{\tt class}\ A
  public:
    A(int k = 5) : data(5) \{ \}
    int set(int k) { return (data = k); }
    int get( ) const { return data; }
    void print() const { cout ≪ data ≪ endl; }
  private:
    int data;
};
                                                                             // Line #15
class B: public A
{
  public:
    int scale(int s) { return set(s * get()); }
};
class C: public B
  public:
    int add(int j) { return set(j + get()); }
};
void output(const A& a) { a.print( ); }
int main( )
{
    C x;
    x.scale(2);
    x.add(3);
    output(x);
    return 0;
}
```

Given the above program, answer the following questions.

(a)	[2 points] What is the output of the program?
	Answer:
(b)	[3 points] If line #15 is changed to
	class B: protected A
	will the program still compile with no error(s)? If yes, what is the output then? If not which statement(s) will not compile and explain briefly why?
	Answer:
(c)	[3 points] If line #15 is changed to
	class B: private A
	will the program still compile with no error(s)? If yes, what is the output then? If not which statement(s) will not compile and explain briefly why?
	Answer:

## Problem 7 [9 points] Polymorphism and Dynamic Binding

```
#include <iostream>
using namespace std;
class Shape
{
  public:
    Shape() { cout \ll "New Shape" \ll endl; }
    virtual \simShape() { cout \ll "\simShape" \ll endl; }
    virtual Shape* duplicate( ) const { return new Shape; }
    virtual void print() const { cout ≪ "Simple Shape" ≪ endl; }
 };
class Box: public Shape
{
  public:
    Box() \{ cout \ll "New Box" \ll endl; \}
    virtual \simBox() { cout \ll "\simBox" \ll endl; }
    virtual Shape* duplicate( ) const { return new Box; }
    virtual void print( ) const { cout ≪ "Simple Box" ≪ endl; }
};
int main( )
{
    Shape* shape = new Box;
    Box* box = dynamic_cast < Box*>(shape→duplicate());
    shape \rightarrow print();
    delete shape;
    delete box;
    return 0;
}
```

#### Problem 8 [22 points] Polymorphism and Dynamic Binding

This question deals with a simple course management system for HKUST students and you are asked to design C++ classes for various types of courses that satisfy the following description and requirements. Firstly, all HKUST courses have lecture session. However, some courses also have lab session, while some other courses have tutorial session.

In your design, you only need to store and print the schedule of each course in addition to its code. All data members should be of the type string (from the C++ string class). Moreover, all member functions should be implemented inside the class definitions as inline member functions.

That is, you are to design the following three classes:

- Course: The base class for all courses, and all courses have lectures.
  - It stores and prints the lecture schedule.
- CourseL: The class for courses with only lecture and lab.
  - It should store and print both the lecture and lab schedules.
- CourseT: The class for courses with only lecture and tutorial.
  - It should store and print both the lecture and tutorial schedules.

You should implement a C++ class for each of the three types of courses by applying the concepts of class inheritance, polymorphism, and dynamic binding so that the following driver program will compile, run, and produce the output below.

And the output of the program should be:

The schedule of COMP3041: Lecture time is TuTh Lab time is Mon The schedule of COMP3711: Lecture time is TuTh Tutorial time is Wed

(a) [8 points] Implement the class Course which will be saved in the "Course.h" file.

Answer: /\* File "Course.h" \*/

(b) [6 points] Implement the class CourseL which will be saved in the "CourseL.h" file.

Answer: /\* File "CourseL.h" \*/

(c) [6 points] Implement the class CourseT which will be saved in the "CourseT.h" file. Answer: /\* File "CourseT.h" \*/ (d) [2 points] Now there are some new courses that have both lab and tutorial sessions. How would you design a new C++ class, say, CourseLT for such new courses, and add it to the management system so that you may best re-use the available code (you have written above)? You only need to sketch your solution in not more than 60 words. YOU DO NOT NEED TO WRITE ANY C++ CODE NOR PSEUDO-CODE. Answer:

## Problem 9 [22 points] Abstract Base Class and Inheritance

This problem involves an abstract base class called 'Question' and two classes 'TF\_Question' and 'MC\_Question' which are derived from 'Question' by public inheritance. Below are the header files of all the 3 classes.

```
/* File: question.h */
#ifndef QUESTION_H
#define QUESTION_H
#include <iostream>
#include <string>
using namespace std;
class Question
  public:
    Question(string s): text(s) { }
    virtual ∼Question() { }
    virtual void display() const { cout ≪ text ≪ endl; }
    // The function cout a prompt that depends on the actual question type,
    // and the user has to input an answer via cin
    virtual bool check_answer() const = 0;
  private:
                                                                    // Question text
    string text;
};
                                                                   // QUESTION_H
#endif
```

```
/* File: tf-question.h */
#ifndef TF_QUESTION_H
#define TF_QUESTION_H
#include "question.h"
class TF_Question: public Question
  public:
    TF_Question(string s, bool a);
                                                    // s is the text, a is the answer
    \simTF_Question();
    virtual void display( ) const;
    virtual bool check_answer( ) const;
  private:
    bool answer;
};
#endif
                                                               // TF_QUESTION_H
/* File: mc-question.h */
#ifndef MC_QUESTION_H
#define MC_QUESTION_H
#include "tf-question.h"
class MC_Question: public Question
{
  public:
    MC_Question(string s, char a);
                                                    // s is the text, a is the answer
    \simMC_Question();
    virtual void display( ) const;
    virtual bool check_answer( ) const;
  private:
                                                              // 'A', 'B', 'C' or 'D'
    char answer;
                                                    // Always assume 4 choices only
    TF_Question* choice[4];
                                            // j=0 => choice 'A', j=1 => 'B', etc.
    TF_Question* add_choice(int j);
};
                                                               // MC_QUESTION_H
#endif
```

#### Notice that

- for all parts of this problem, you may assume that the user will always enter correct information in the correct format, and you don't need to check for invalid inputs.
- the implementation of class Question is complete in its header file, and thus, there is no need for a "question.cpp" file.
- during the call of check\_answer(), users will be prompted for an answer to the question and the prompt differs for different types of questions.
- each MC\_Question object always owns 4 choices which are represented by TF\_Question objects. The choices are added during the construction of an MC\_Question object by calling its private add\_choice() member function. You may assume that the choices are always added with answers matching the correct answer given to the constructor of the MC\_Question object.

Below is the testing program "question-test.cpp" for the 3 classes, and it is compiled by the following command to produce the executable program called "question-test".

```
gcc -o question-test question-test.cpp tf-question.cpp mc-question.cpp
```

```
/* File: question-test.cpp */
#include "question.h"
#include "tf-question.h"
#include "mc-question.h"
int main( )
{
     Question* q[2];
     q[0] = new TF_Question("Are you happy with COMP2012?", true);
     q[1] = \text{new MC\_Question}(\text{"Among the following, who is a Chinese?", 'C')};
     cout \ll endl;
     for (int j = 0; j < 2; ++j)
     {
          \operatorname{cout} \ll \operatorname{"QUESTION"} \ll j+1 \ll \operatorname{endl} \ll \operatorname{"-----} \ll \operatorname{endl};
          q[j] \rightarrow display();
          cout \ll (q[j] \rightarrow check\_answer())? "Correct\n\n": "Incorrect\n\n");
     }
     return 0;
}
```

A sample run is given as follows:

```
Enter choices for the MC question:
Among the following, who is a Chinese?
Enter choice A followed by the answer (1 for yes, 0 for no): Mozart 0
Enter choice B followed by the answer (1 for yes, 0 for no): Newton 0
Enter choice C followed by the answer (1 for yes, 0 for no): Confucius 1
Enter choice D followed by the answer (1 for yes, 0 for no): Picasso 0
QUESTION 1
-----
This is a True/False Question: Are you happy with COMP2012?
Answer "yes" or "no": yes
Correct
QUESTION 2
This is a Multiple-Choice Question:
(A) Mozart
(B) Newton
(C) Confucius
(D) Picasso
Answer 'A', 'B', 'C' or 'D': B
Incorrect
```

Based on the given information, complete the implementation of TF\_Question class and MC\_Question class in their respective .cpp files, namely, 'tf-question.cpp' and 'mc-question.cpp' respectively.

(a) [6 points] Implement all member functions of the class  $TF_Question$  in a separate file called "tf-question.cpp".

Answer: /\* File "tf-question.cpp" \*/

(b) [16 points] Implement all member functions of the class  $MC_Question$  in a separate file called "mc-question.cpp".

Answer: /\* File "mc-question.cpp" \*/
